Note: Within nine months from the publication of the mention of the grant of the European patent, any person may give notice to the European Patent Office of opposition to the European patent granted. Notice of opposition shall be filed in a written reasoned statement. It shall not be deemed to have been filed until the opposition fee has been paid (Art. 99(1) European patent convention).

## Description

This invention relates to a self-starting portable tool comprising a housing, an elongated cylinder in said housing, a piston having an upper face and a lower face, said piston being mounted in said cylinder to be driven between an upper position of rest and a lowermost position and forming a motor member, a working member attached to said piston, a combustion chamber formed within said housing, a turbulence generator in said chamber, means for providing a fuel and air mixture in said chamber, means for igniting and exploding said mixture in said combustion chamber to drive said piston through a driving stroke from said upper position to said lowermost position to operate said working member, and return means for causing said piston to move upwardly from said lowermost position to said uppermost position of rest.

A self-starting portable tool of this type is known from DE-A 2 422 773. This reference discloses a fastener tool in which the piston must be manually returned each time. As soon as the pressure drops in the cylinder, the main valve assembly drops from the elevated position to the closed position. Therefore, if the piston begins to rise, there will be a rapid rise to atmospheric pressure, because the upper surface of the piston is working in a closed space of relatively small volume. The combustion occurs in a zone adjacent to the main valve assembly and the piston is exposed to the pressure only after the pressure rise in that zone is enough to lift the main valve off its seat. At the end of each driving stroke of the tool, the piston is at the end of its power stroke, in which position the lower surface of the piston rests against a resilient or elastomeric bumper disposed within the lower end of the cylinder.

The object of the present invention is an improvement of the above-mentioned known type of portable gas-powered tool in such a manner, that a compression chamber in the lower end of the main cylinder functions as a bumper to prevent the piston from striking the support casting and means are provided for moving the piston upwardly.

The invention achieves this aim by the characterization that the upper face of said piston defines a wall portion of said combustion chamber, said return means including port means in said elongated cylinder between its ends for communicating said cylinder with ambient atmosphere and being disposed below said upper position of rest and above said lowermost position of said piston, such that when said piston is driven toward said lowermost position, said piston moves past said

outlet means thereby to place said combustion chamber in communication with said port means to exhaust a portion of combustion gases from said combustion chamber to ambient atmosphere and cause a reduction in temperature of the combustion gases remaining in the combustion chamber and said return means further including bumper means at the lower end of the cylinder for initially moving said piston upwardly from said lowermost position, said combustion chamber above said upper face being out of communication with ambient atmosphere during the further return of said piston to said upper position of rest, said further return of said piston to said upper position of rest being substantially caused by said return means producing an upwardly acting pressure differential on said upper and lower faces of said piston induced by the reduction in temperature of the combustion gases above the upper face to produce a sharp reduction of pressure in said combustion chamber to below ambient pressure.

Furthermore, the port means comprise a plurality of ports being located in the lower end of the cylinder. Said port means is in communication with ambient atmosphere when that piston is both thereabove and therebelow through an exhaust valve which opens when the pressure below the piston increases above ambient pressure, and which closes in response to a reduction to pressure below atmosphere pressure internally of the cylinder in the zone of said port means. Said exhaust valve is adapted to open in response to movement of said piston downwardly towards said port means, as well as in response to exposure to said combustion chamber when said piston moves downwardly past said port means.

The portable tool according to the invention includes exhaust valve means located above the bottom of said cylinder for exhausting air beneath the piston through said port means as the piston moves through its driving stroke, the portion of the cylinder below said port means, the piston lower face and the housing adjacent the bottom of the cylinder providing a sealed compression chamber whereby the air below the piston and port means is compressed to form an air bumper to prevent the piston from contacting the housing adjacent the bottom of the cylinder. The section of the housing adjacent the bottom of the cylinder includes a plurality of one-way return valves which open to introduce atmospheric air to assist in moving the piston to its upper position after it has been driven and the combustion gases have been exhausted through port means and a vacuum exists above the piston.

Thus, the invention provides for a compression of the air beneath the piston to provide a bumper preventing the piston from engaging the bottom of

the cylinder. In the absence of the differential pressure across the piston it will remain fixed in place relative to the interior side walls of the main cylinder when it is returned to its driving position by the frictional force between the piston and the inside side walls of the main cylinder.

Numerous other advantages and features of the invention will become readily apparent from the following detailed description of the described embodiments, from the claims, and from the accompanying drawings.

#### Brief Description of the Drawings

Figure 1 is a partial cross-sectional side elevational view of an embodiment of the present invention, a fastener driving tool, and illustrating the position of the principal components before the tool has been fired;

Figure 2 is a partial cross-sectional side elevational view of the fastener driving tool as shown in Figure 1 illustrating the position of the major components located at the lower end of the barrel section at the end of the linear motor driving stroke;

Figure 3 is an enlarged partial cross-sectional side elevational view of the components forming the ignition mechanism of the embodiment of Figure 1; and

Figure 4 is a schematic diagram illustrating the ignition circuit of the embodiment of Figure 1.

#### Detailed Description

This invention is susceptible of being used in many different types of tools. There is shown in the drawings and will herein be described in detail an embodiment of the tools incorporating the invention, with the understanding that this embodiment is to be considered but exemplification, and that it is not intended to limit the invention to the specific embodiment illustrated. The scope of the invention will be pointed out in the claims.

Reference is now made to Figures 1-4, which illustrate a portable fastener driving tool employing the novel linear motor.

Referring first to Figure 1, there is illustrated a fastener driving tool 100, the principal components of which are attached to or carried by a generally hollow housing 102. The housing 102 of the tool 100 has three major sections: a barrel section 108, a graspable, elongated handle section 110 extending horizontally outwardly from a position generally midway of the barrel section, and a base 106 extending under the barrel section and the handle section. Located within the barrel section 108 is a main cylinder 104 in which the linear motor is located. Included in the base 106 is a magazine

assembly 112 holding a row of nails disposed transversely to the path of a fastener driver 132 that is connected to and operated by the linear motor, which in this case is a working piston assembly 130.

The lower end of the barrel section 108 carries a guide assembly 152 which guides the fastener driver towards the workpiece. The magazine 112 supplies fasteners serially under the fastener driver 132 into the guide assembly 152 to be driven into the workpiece. The base 106 also supports a holder 116 containing a plurality of dry cells which form the power source 118.

A fuel tank 114 is mounted between the barrel section 108 and the handle portion 110 of the housing 102. The fuel tank 114 is filled with a liquefied, combustible gas kept under pressure, such as, MAPP gas or propane, which vaporizes when it is discharged into the atmosphere. The fuel tank 114 is supported by a pivoted lower bracket 200 and a fixed, generally U-shaped upper bracket 202. The upper end of the fuel tank 114 carries a valve assembly 204 for metering fuel out of the tank. A flexible plastic cover 210 pivotably joined to a cover member 168 fits into the upper bracket 202 to retain the fuel tank in place. The cover 210 is opened when the fuel tank 114 must be replaced. The cover 210 provides a downward force which snugly holds the lower end of the fuel tank within the lower bracket 200. At this point, it should be noted that the upper bracket 202 has an inside dimension greater than the outside dimension of the fuel tank 114.

In particular, this dimension is selected so that when the upper end of the fuel tank is forced towards the upper end of the barrel section 108 of the housing 102, the valve assembly 204 will be actuated to dispense a metered quantity of fuel. The manner in which this is accomplished will be explained after the interior components of the tool have been described.

#### Barrel Section

At the interior of the lower end of the barrel section 108 of the housing 102, there is located the open-ended cylinder 104. The cylinder will hereinafter be referred to as the "main cylinder". The diameter of the main cylinder 104 relative to the diameter of the barrel section 108 of the housing 102 is such that an open generally annular zone or region 134 is formed. The barrel section of the housing 102 is formed with peripheral openings 103, which allow air to pass freely around the exterior of the main cylinder 104.

The driving piston 130 is mounted within the main cylinder and carries the upper end of the fastener driver 132. The upper end of the barrel

section 108 of the housing 102 carries an electrically powered fan 122 and a main valve mechanism 124, which controls the flow of air between the combustion chamber 120 and atmosphere. The upper end of the housing located above the fan is closed by the cylinder head 126. The main valve mechanism 124 includes an upper cylinder 136, which together with the cylinder head 126, the main cylinder 104, and the piston 130 forms the combustion chamber 120. The electric fan includes a set of blades 123 which are joined to the output shaft of the electric motor 122.

The main cylinder 104 is closed at its lower end by a cup-shaped support casting 128 that is suitably supported in the barrel section. Located near the bottom of the cylinder 104 are a series of exhaust ports 156 that are closed off by exhaust valves 172 that are located to control the flow of gas out of the cylinder 104 when the piston linear motor 130 passes the ports 156. Connected to the cylinder 104 adjacent the ports 156 is an annular ring-shaped casting 173. At the bottom of the cylinder 104, a seal 158 is used to plug the center of the support casting 128. Also located in the support casting are a plurality of ports 176 which interconnect the bottom of the cylinder 104 with the chamber 146 in which there is located a spring 148 for reasons to be described hereinafter.

The piston 130 moves between the opposite ends of the main cylinder 104. The upward and downward movement of the piston defines the driving and return strokes of the piston. As previously mentioned, valves 172 permit exhausting of the gas above the piston when the piston passes the ports 156 and the valves 174, which remain closed during the downward movement of the piston, provide for a compression of the air beneath the piston to provide a bumper preventing the piston from engaging the bottom of the cylinder. These valves 174 also function to open and introduce air into the space below the piston after the piston begins to be returned to its driving position. The piston 130 carries the fastener driver, which extends through the seal 158 and into the guide assembly 152. The guide assembly is configured to pass individual fasteners 154 that are disposed therein by the magazine 112, so that when the piston 130 is driven through its driving stroke a fastener is driven into a workpiece.

It is to be noted that the piston 130 includes a pair of O-rings that are sized so that the frictional force between the piston and the inside sidewalls of the main cylinder is sufficiently great so that in the absence of the differential pressure across the piston it will remain fixed in place relative to the interior sidewalls of the main cylinder when it is returned to its driving position. The upward movement of the piston 130 is limited by an overhang of

the cylinder 104.

The cylinder 136 constituting the valve control for the combustion chamber is free to move between the lower position shown in solid lines in Figure 2 wherein the combustion chamber is open to atmosphere to permit air to flow in, as shown by the arrows 226 and an upper position shown in dotted lines wherein the combustion chamber is sealed off from the atmosphere by the O-ring 162 provided in the cap 126 and the O-ring 160 provided in the main cylinder 104. Air is thus free to enter through the upper opening 140 when the tool is in the position shown in Figure 1 and expanded combustion gas is free to exit from the combustion chamber 120 through the opening 138. The downward movement of the cylinder 136 is limited by engagement of inwardly extending fingers 170 on cylinder 136 with cylinder 104.

It is essential to provide turbulence in the combustion chamber 120 to maximize the operating efficiency of the tool.

When the chamber 120 is opened to atmosphere, the position and configuration of the rotating fan blades 123 causes a differential pressure across the combustion chamber 120. This action creates movement of air in the chamber 120 and forces air in (arrow 226) through the upper openings 140 and out (arrow 224) through the lower openings 138. When the combustion chamber is sealed off from the atmosphere, and turbulence is created in the combustion chamber by rotation of fan 123, fuel is injected and the mixture is ignited. The flame propagation enhanced by the turbulence substantially increases the operating efficiency of the tool.

To insure that the tool cannot be fired until it is in engagement with the workpiece, the movement of the cylinder 136 is effected by a bottom trip mechanism which is operated when the tool is brought into contact with a workpiece into which a fastener is to be driven. In the embodiment illustrated in Figure 1, it includes a spring-loaded casting to which are connected lifting rods that are used to raise and lower the cylinder 136.

Specifically, a Y-shaped casting 142 is located in the chamber 146 between the guide assembly 152 and the lower end of the support casting 128. Connected to the casting are three lifting rods 144A, B and C which interconnect the casting 142 to the cylinder 136. Extending downwardly from the casting 142 is a cylinder mount 147. The spring 148 in the chamber 146 acts to bias the casting 142 into the position shown in Figure 1. Located within the cylindrical mount 147 is the main lifting rod 150 which when moved upwardly moves the rods 144A, B and C upwardly, which carries with it the cylinder 136 to close off the combustion chamber. The design is selected so that engagement of

the main lift rod with the workpiece raises the cylinder 136 the prescribed amount to the broken line position shown in Figure 2 to seal the combustion chamber. Accordingly, when the tool is lifted off from the workpiece, the spring 148 biases the lifting rod 150 downwardly to move the cylinder 136 to the full line position shown in Figure 1 wherein the combustion chamber is open to atmosphere.

All the major components fitting within the barrel section 108 of the housing 102 have been described with the exception of those components that are joined to the cylinder head 126.

The cylinder head 126 carries the electric fan 122, a spark plug 164, and provides an internal passageway 166 through which fuel is injected into the combustion chamber 120.

The components located within the handle section 110 of the housing 102 will now be described.

#### Handle Section

The handle section 110 contains the controls used to operate the tool 100. In particular, the handle section 110 contains a "deadman's" switch 178, a trigger mechanism 180, a piezoelectric firing circuit 182, which activates the spark plug 164, a portion of a fuel ejecting mechanism 184, which introduces fuel into the combustion chamber 120 via the passageway 166 in the cylinder head 126, and a firing circuit interlock mechanism 188, which locks and unlocks the trigger mechanism 180.

The deadman's switch 178 is mounted at the top of the handle 110. It is suitably connected through appropriate mechanism to operate the electric motor 122 to drive the fan 123. Thus, it can be seen that when the user of the tool grips the handle in the forward position, the fan 122 is actuated to provide turbulence in the combustion chamber 120.

The trigger mechanism 180 mounted in the handle includes a lever 190 which is pivotally connected to a piezo-electric firing circuit 182 by a pin 192. The trigger button 194 is joined by a pivot pin 196 to the fuel ejecting mechanism 184.

The fuel ejecting mechanism 184, which functions to introduce a prescribed metered amount of fuel into the combustion chamber, includes an actuating link 212 which interconnects the trigger 194 to a camming mechanism 214. The operation of the trigger through the linkage 212 and camming mechanism 214 acts to move the fuel tank 114 to the left, which results in depression of the outlet nozzle 206 to introduce a metered amount of fuel into the passageway 166 from the metered valve assembly 204. It is noted that the tank 114 is retained in position by means of the cover 210 which is interengaged with the upper bracket 202.

When the trigger is released, the spring 208 acts to return the fuel tank to the position in Figure 1.

The fuel injected into the combustion chamber 120 is ignited by a spark plug 164 powered from the piezoelectric firing circuit 182. Figures 3 and 4 illustrate the firing circuit 182. According to the piezoelectric effect, voltage is produced between opposite sides of certain types of crystals 182A, 182 B when they are stuck or compressed. Here a camming mechanism actuated by the lever 190 and pivot pin 192 is used to force together the two crystals 182A, 182B. An adjusting screw 183 sets the preload to the assembly. A schematic diagram of the electrical circuit between the spark plug 164 and the piezo-electric firing circuit 182 is illustrated in Figure 4 and includes a capacitor C and a rectifier R. The capacitor C stores energy until the spark discharges, and the rectifier R permits spark to occur when the trigger is squeezed and not when the trigger is released. The piezo-electric firing circuit 182 is tripped when the lever 190 is raised upwardly by the trigger mechanism 180. Before the firing circuit can be refired or recycled, the lever 190 must be lowered to cock the cam used to force the two crystals 182A and 182B together.

There remains to describe the firing circuit interlock mechanism which precludes firing of the tool until all components are in their proper position. This includes links 216 which are connected to the trigger mechanism 180 by a tension spring 220 and a pivot pin 222. Connecting links 216 are located on opposite sides of the fuel tank 114. It can be appreciated that with the pin 218B located in the slotted opening 198 of the handle 110 that until the cylinder 136 is moved upwardly by the upward movement of the rods, 144A, B, and C, the trigger cannot be actuated to form the spark to ignite the fuel in the combustion chamber. Upward movement of the rods 144A, B, and C moves the links 216 upwardly and withdraws the pin 218B out of the slot 198, thus permitting the trigger 194 to be moved upwardly to introduce the metered fuel into the combustion chamber and actuate the piezoelectric circuit. Stated another way, the trigger cannot be actuated to introduce fuel and create a spark until the workpiece is engaged to move the guide assembly upwardly, which moves the casting 142 upwardly to free the trigger 194.

Briefly, the tool disclosed in Figures 1-4 operates as follows.

Grasping of the tool 110 engages the deadman's switch 178 to start the fan motor 122 to rotate the blades 123 to provide turbulence in the combustion chamber 120. With the electric fan running, a differential pressure is produced across the combustion chamber, which acts to force fresh air in (arrow 226) through the upper openings 140

and out (arrow 224) through the lower opening 138. The rotating fan blades produce a swirling turbulent effect within the combustion chamber. Any combustion gases remaining in the combustion chamber due to the previous operation of the tool are thoroughly scavenged and discharged from the combustion chamber by operation of the electric fan 122.

When the tool is positioned on the workpiece, the main lifting rod is depressed, as shown in Figure 23, which overcomes the force of the biasing spring 148 to move lifting rods 144A, B, and C, and the cylinder 136 from its lower position shown in solid lines to its upper position shown in dotted lines to seal off the combustion chamber 120. This upward movement of the lifting rods also activates the firing circuit interlock mechanism 188. That is to say that the links 216 and associated pins 218B are pulled out of the slot 198, thus permitting the trigger 194 to be moved upwardly. Upward movement of the trigger 194 actuates the fuel injecting mechanism by moving the container to the left through the action of the linkage 212 and camming mechanism 214. This results in engaging the metering valve assembly 204 to introduce a metered amount of fuel into the passageway 166 and the combustion chamber 120. During upward movement of the trigger 194, the crystals 182A and 182B are forced together to actuate the piezo-electric firing circuit 182, which fires the spark plug 164 in the combustion chamber 120.

The rapid expansion of the exploding air and fuel mixture pressurizes the upper face 130A of the piston 130 and drives the fastener driver downwardly wherein it forces a fastener 154 into a workpiece. In addition, the movement of the piston 130 through its driving stroke compresses the air within the main cylinder 104 bounded by the lower face of 130B of the piston and the inside of support casting 128. As the pressure increases below the piston 130, the exhaust valve means 172 on the sidewalls of the main cylinder 104 pops open. As long as the exhaust valve means 172 is open, the pressure cannot build up on the lower face 130B of the piston 130. When the piston 130 passes below the ports 156, the air bounded by the lower face of the piston and the inside of the support casting is now isolated from the atmosphere, and the pressure on the lower face 130B of the piston rapidly increases. Effectively, a compression chamber has been formed in the lower end of the main cylinder which functions as a bumper to prevent the piston from striking the support casting 128.

Once the piston 130 has passed the ports 156 on the sidewalls of the main cylinder 104, the combustion gases are free to flow out of the main cylinder 104 through the exhaust valve means 172 to the atmosphere. The temperature of the gases in

the combustion chamber rapidly drops from approximately 2000° F (1093° C) to 70° F (21.1° C) in about 70 milliseconds due to the expansion of the gases as the piston moves downwardly and the cooling effect of the walls surrounding the expanding gases, and this sudden temperature drop produces a vacuum within the combustion chamber 120. Once the pressure within the combustion chamber is below atmosphere, the exhaust valve means 172 shuts off.

As soon as the pressure on the upper face 130A of the piston 130 is less than the pressure on the lower face 130B, the piston will be forced upwardly through its return stroke. Initially, this upward movement is caused by the expansion of the compressed air within the compression chamber (see Figure 3). Subsequent movement is caused by the pressure of the atmosphere, since the thermal vacuum formed within the combustion chamber 120 is on the order of a few psia  $1 \text{ psia} \approx 6.89 \cdot 10^3 \text{ Pa}$ . Additional air is supplied to the lower face 130B of the piston 130 through the return valves 174 which are opened by the atmospheric pressure. The piston 130 will continue upwardly until it engages the lip on the cylinder and will remain suspended at the upper end of the main cylinder by virtue of the frictional engagement between the sealing rings and the cylinder wall plus the force of the seal 158 on the fastener driver 132.

If the tool 100 is then lifted clear of the workpiece the main lifting rod 150 is forced outwardly by its main biasing spring 148. Since the electric fan 123 is still in operation, any remaining combustion gases are forced out of the lower openings 138, and fresh air is drawn in through the upper openings 140. This prepares the tool for firing another fastener into the workpiece. When the trigger button 194 is released the piezo-electric system 182 is reset or cooked for a subsequent firing period. When the main lifting rod 150 is driven downwardly by the biasing spring 148, the lock pin 218B within the firing circuit interlock mechanism 188 is forced back into the slotted opening 198 in the housing. This prevents subsequent operation of the trigger mechanism until the tool 100 is properly positioned on the workpiece and the combustion chamber is isolated from the atmosphere.

A portable gas-powered tool with this novel linear motor can be used for a variety of purposes, depending on the attachments connected to the motor. For example, as illustrated in the embodiment of Figures 1-4, it can be used to drive fasteners. Also, of course, attachments can be connected to the working member of the linear motor for shearing tree limbs, connecting hog rings, animal tags, piercing holes, marking metal plates, etc. In substance, it can be used anywhere where a large force is required. As stated, this tool is fully porta-

ble, can be light in weight, and thus can be used anywhere independent of the need for an external source of power, such as compressed air.

The novel motor is made possible in a relatively small portable tool by the creation of turbulence in the combustion chamber prior to and during combustion. This has not been done before in a portable tool and while it is acknowledged that internal combustion engines are notoriously old, these all require an external source of power in order to start the engine. The fan causes the air and fuel to be mixed to a generally homogeneous state under atmospheric conditions, and continued operation of the fan increases the burning speed of the fuel-air mixture in the combustion chamber prior to and during movement of the working member. In this tool, no external source of power is required and starting of the tool is totally independent of movement of the working member. This tool utilizes liquified gas, and thus is very economical to operate. Actually, it is about one half the cost of operating a pneumatic tool powered by a gasoline driven air compressor. As stated above, a relatively small portable tool adaptable for many uses can be designed employing the invention.

#### Claims

1. A self-starting portable tool comprising a housing (102),  
an elongated cylinder (104) in said housing (102),  
a piston (130) having an upper face (130A) and a lower face (130B),  
said piston (130) being mounted in said cylinder (104) to be driven between an upper position of rest and a lowermost position and forming a motor member,  
a working member (132) attached to said piston (130),  
a combustion chamber (120) formed within said housing (102), a turbulence generator (122) in said chamber (120),  
means for providing a fuel and air mixture in said chamber (120),  
means (164) for igniting and exploding said mixture in said combustion chamber (120) to drive said piston (130) through a driving stroke from said upper position to said lowermost position to operate said working member (132),  
and return means for causing said piston (130) to move upwardly from said lowermost position to said uppermost position of rest,  
characterized in that  
the upper face (130A) of said piston (130) defines a wall portion of said combustion chamber (120),

said return means including port means (156) in said elongated cylinder (104) between its ends for communicating said cylinder (104) with ambient atmosphere and being disposed below said upper position of rest and above said lowermost position of said piston (130), such that when said piston (130) is driven towards said lowermost position, said piston (130) moves past said outlet means (156) thereby to place said combustion chamber (120) in communication with said port means (156) to exhaust a portion of combustion gases from said combustion chamber (120) to ambient atmosphere and cause a reduction in temperature of the combustion gases remaining in the combustion chamber (120) and said return means further including bumper means at the lower end of the cylinder (104) for initially moving said piston (130) upwardly from said lowermost position, said combustion chamber (120) above said upper face (130A) being out of communication with ambient atmosphere during the further return of said piston (130) to said upper position of rest, said further return of said piston (130) to said upper position of rest being substantially caused by said return means producing an upwardly acting pressure differential on said upper and lower faces (130A, 130B) of said piston (130) induced by the reduction in temperature of the combustion gases above the upper face (130A) to produce a sharp reduction of pressure in said combustion chamber (120) to below ambient pressure.

2. A self-starting portable tool in accordance with claim 1, wherein said port means comprises a plurality of ports (156).
3. A self-starting portable tool in accordance with claim 1, wherein said port means (156) is located in the lower end of the cylinder (104) but above the bottom thereof.
4. A self-starting portable tool in accordance with claim 1, wherein said port means is in communication with ambient atmosphere when said piston (130) is both thereabove and therebelow through an exhaust valve (172) which opens when the pressure below the piston (130) increases above ambient pressure, and which closes in response to a reduction to pressure below atmosphere pressure internally of the cylinder (104) in the zone of said port means (156).
5. A self-starting portable tool in accordance with claim 4, wherein said exhaust valve (172) is

adapted to open in response to movement of said piston (130) downwardly towards said port means (156), as well as in response to exposure to said combustion chamber (120) when said piston (130) moves downwardly past said port means (156).

6. A self-starting portable tool as set forth in claim 1, including exhaust valve means (172) located above the bottom of said cylinder (104) for exhausting air beneath the piston (130) through said port means (156) as the piston moves through its driving stroke, the portion of the cylinder (104) below said port means (156), the piston lower face (130B) and the housing (102) adjacent the bottom of the cylinder (104) providing a sealed compression chamber (146) whereby the air below the piston (130) and port means (156) is compressed to form an air bumper to prevent the piston (130) from contacting the housing (102) adjacent the bottom of the cylinder (104).
7. A self-starting portable tool as set forth in claim 4, in which the section of the housing (102) adjacent the bottom of the cylinder (104) includes a plurality of one-way return valves (174) which open to introduce atmospheric air to assist in moving the piston (130) to its upper position after it has been driven and the combustion gases have been exhausted through port means (156) and a vacuum exists above the piston (130).

#### Revendications

1. Un outil portatif à auto-démarrage comprenant:
  - un carter (102),
  - un cylindre allongé (104) dans ledit carter (102),
  - un piston (130) comportant une face supérieure (130A) et une face inférieure (130B),
  - ledit piston (130) étant monté dans ledit cylindre (104) de façon à être entraîné entre une position supérieure de repos et une position limite inférieure et formant un élément moteur,
  - un élément de travail (132) fixé sur ledit piston (130),
  - une chambre de combustion (120) formée à l'intérieur dudit carter (102),
  - un générateur de turbulence (122) dans ladite chambre (120),
  - des moyens pour créer un mélange de carburant et d'air dans ladite chambre (120),
  - des moyens (164) pour produire l'alluma-

ge et l'explosion dudit mélange dans ladite chambre de combustion (120) afin d'entraîner ledit piston (130) dans une course d'entraînement depuis ladite position supérieure jusqu'à ladite position limite inférieure afin d'actionner ledit élément de travail (132),

- et des moyens de retour pour faire en sorte que ledit piston (130) se déplace vers le haut depuis ladite position limite inférieure jusqu'à ladite position limite supérieure de repos,
- caractérisé en ce que :
- la face supérieure (130A) dudit piston (130) définit une partie de paroi de ladite chambre de combustion (120),
- lesdits moyens de retour comprenant des moyens formant orifices (156) formés dans ledit cylindre allongé (104) entre ses extrémités pour mettre en communication ledit cylindre (104) avec l'atmosphère ambiante et étant disposés en dessous de ladite position supérieure de repos et au-dessus de ladite position limite inférieure dudit piston (130) de telle sorte que, quand ledit piston (130) est entraîné en direction de ladite position limite inférieure, ledit piston (130) se déplace après lesdits moyens formant orifices (156) de manière à mettre ladite chambre de combustion (120) en communication avec lesdits moyens formant orifices (156) pour décharger une partie des gaz de combustion de ladite chambre de combustion (120) dans l'atmosphère ambiante et pour produire une réduction de la température des gaz de combustion restant dans la chambre de combustion (120) et
- lesdits moyens de retour comprennent en outre un moyen formant tampon, situé à l'extrémité inférieure du cylindre (104) pour déplacer ledit piston (130) vers le haut à partir de ladite position limite inférieure, ladite chambre de combustion (120), au-dessus de ladite face supérieure (130A), n'étant plus en communication avec l'atmosphère ambiante pendant la suite du retour dudit piston (130) jusqu'à ladite position supérieure de repos, ladite suite de retour dudit piston (130) jusqu'à ladite position supérieure de repos étant causée dans l'essentiel par ledit moyen de retour produisant sur lesdites faces supérieure et inférieure (130A, 130B) dudit piston (130) une différence de pression agissant vers le haut et engendrée par la réduction de tempé-

- rature des gaz de combustion au-dessus de la face supérieure (130A) afin de produire une forte réduction de pression dans ladite chambre de combustion (120) jusqu'en dessous de la pression ambiante. 5
2. Un outil portatif à auto-démarrage selon la revendication 1, dans lequel lesdits moyens formant orifices comprennent une pluralité d'orifices (156). 10
3. Un outil portatif à auto-démarrage selon la revendication 1, dans lequel lesdits moyens formant orifices (156) sont situés à l'extrémité inférieure du cylindre (104) mais au-dessus de son fond. 15
4. Un outil portatif à auto-démarrage selon la revendication 1, dans lequel lesdits moyens formant orifices sont en communication avec l'atmosphère ambiante, lorsque ledit piston (130) se trouve à la fois au-dessus et en dessous d'eux, par l'intermédiaire d'une soupape d'échappement (172) qui s'ouvre quand la pression en dessous du piston (130) augmente au-dessus de la pression ambiante, et qui se ferme en réponse à une réduction de la pression en dessous de la pression atmosphérique à l'intérieur du cylindre (104) et dans la zone desdits moyens formant orifices (156). 20
5. Un outil portatif à auto-démarrage selon la revendication 4, dans lequel ladite soupape d'échappement (172) est adaptée pour s'ouvrir en réponse à un mouvement dudit piston (130) vers le bas en direction desdits moyens formant orifices (156), et également en réponse à une exposition à ladite chambre de combustion (120) quand ledit piston (130) se déplace vers le bas au-delà desdits moyens formant orifices (156). 25
6. Un outil portatif à auto-démarrage selon la revendication 1, comprenant un moyen (172) formant soupape d'échappement et situé au-dessus du fond dudit cylindre (104) pour décharger de l'air en dessous du piston (130) par l'intermédiaire desdits moyens formant orifices (156) lorsque le piston se déplace dans sa course d'entraînement, la partie du cylindre (104), située en dessous desdits moyens formant orifices (156), la face inférieure (130B) du piston et le carter (102) adjacent au fond du cylindre (104) créant une chambre de compression hermétique (146) de façon que l'air situé en dessous du piston (130) et des moyens formant orifices (156) soient compri- 30

més pour former un tampon d'air empêchant le piston (130) d'entrer en contact avec le carter (102) dans une zone adjacente au fond du cylindre (104).

7. Un outil portatif à auto-démarrage selon la revendication 4, dans lequel la section du carter (102) adjacente au fond du cylindre (104) comporte une pluralité de clapets unidirectionnels (174) qui s'ouvrent pour introduire de l'air atmosphérique afin d'assister le mouvement du piston (130) jusque dans sa position supérieure après qu'il a été entraîné et après que les gaz de combustion ont été déchargés par l'intermédiaire des moyens formant orifices (156) et qu'un vide existe au-dessus du piston (130).

#### Patentansprüche

1. Selbstanlassendes tragbares Werkzeug, bestehend aus einem Gehäuse (102), einem sich längs erstreckenden Zylinder (104) in dem Gehäuse (102), einem Kolben (130) mit einer Oberseite (130 A) und einer Unterseite (130 B), wobei der in dem Zylinder (104) angeordnete Kolben (130) zwischen einer oberen Ruhestellung und einer untersten Stellung antreibbar ist und ein Motororgan bildet, einem Arbeitsorgan (132), das an dem Kolben (130) angebracht ist, einer Verbrennungskammer (120), die innerhalb des Gehäuses (102) gebildet ist, einem Turbulenzgenerator (122) in der Kammer (120), einer Vorrichtung zum Zurverfügungstellen eines Brennstoff- und Luftgemisches in der Kammer (120), einer Vorrichtung (164) zum Zünden und Explodieren der Mischung in der Verbrennungskammer (120), um den Kolben (130) durch einen Treibhub aus der oberen Stellung in die unterste Stellung anzutreiben und das Arbeitsorgan (132) zu betätigen, und einer Rückstellvorrichtung zum Aufwärtsbewegen des Kolbens (130) aus seiner untersten Stellung in die oberste Ruhestellung, dadurch gekennzeichnet, daß die Oberseite (130 A) des Kolbens (130) einen Wandteil der Verbrennungskammer (120) bildet, die Rückstellvorrichtung eine Öffnung (156) in dem sich längs erstreckenden Zylinder (104) zwischen dessen Enden zur Herstellung einer Verbindung des Zylinders (104) mit der Umgebungsatmosphäre umfaßt und unterhalb der oberen Ruhestellung sowie oberhalb der unter- 35

- sten Stellung des Kolbens (130) angeordnet ist, derart, daß, wenn der Kolben (130) in Richtung seiner untersten Stellung angetrieben wird, der Kolben (130) sich an der Auslaßvorrichtung (156) vorbeibewegt, wodurch die Verbrennungskammer (120) mit der Öffnungseinrichtung (156) in Verbindung gebracht wird, um einen Teil der Verbrennungsgase aus der Verbrennungskammer (120) in die Umgebungsatmosphäre auszutreiben und die Temperatur der in der Verbrennungskammer (120) verbleibenden Verbrennungsgase zu verringern, und die Rückstellvorrichtung außerdem eine Dämpfervorrichtung am unteren Ende des Zylinders (104) für eine Anfangsbewegung des Kolbens (130) aus der untersten Stellung nach oben umfaßt, wobei die Verbindung der Verbrennungskammer (120) oberhalb der Oberseite (130 A) mit der umgebenden Atmosphäre während der weiteren Rückstellbewegung des Kolbens (130) in die obere Ruhestellung unterbrochen ist, die weitere Rückstellbewegung des Kolbens (130) in die obere Ruhestellung im wesentlichen durch die Rückstellvorrichtung verursacht ist, welche ein aufwärts wirkendes Druckdifferential auf die oberen und unteren Seiten (130 A, 130 B) des Kolbens (130) hervorruft, das durch die Verringerung der Temperatur der Verbrennungsgase oberhalb der Oberseite (130 A) induziert wird, um eine starke Druckverringern in der Verbrennungskammer (120) unter den Umgebungsdruck zu erzeugen.
2. Selbstanlassendes tragbares Werkzeug nach Anspruch 1, bei dem die Öffnungseinrichtung mehrere Öffnungen (156) umfaßt.
  3. Selbstanlassendes tragbares Werkzeug nach Anspruch 1, bei dem die Öffnungseinrichtung (156) in dem unteren Ende des Zylinders (104), jedoch oberhalb des Bodens desselben angeordnet ist.
  4. Selbstanlassendes tragbares Werkzeug nach Anspruch 1, bei dem die Öffnungseinrichtung (156), wenn der Kolben (130) sowohl oberhalb als auch unterhalb derselben liegt, mit der Umgebungsatmosphäre über ein Auslaßventil (172) in Verbindung steht, das sich öffnet, wenn der Druck unterhalb des Kolbens (130) über den Umgebungsdruck ansteigt, und das sich in Abhängigkeit von einer Druckverringern unter den Atmosphärendruck innerhalb des Zylinders (104) in dem Bereich der Öffnungseinrichtung (156) schließt.
  5. Selbstanlassendes tragbares Werkzeug nach

Anspruch 4, bei dem das Auslaßventil (172) so angepaßt ist, daß es sich in Abhängigkeit von der Bewegung des Kolbens (130) nach unten in Richtung der Öffnungseinrichtung (156) ebenso, wie in Verbindung mit der Verbrennungskammer (120) öffnet, wenn der Kolben (130) sich an der Öffnungseinrichtung (156) vorbei nach unten bewegt.

6. Selbstanlassendes tragbares Werkzeug nach Anspruch 1, umfassend ein Auslaßventil (172), das über dem Boden des Zylinders (104) zum Ausstoßen von Luft unter dem Kolben (130) durch die Öffnungseinrichtung (156) angeordnet ist, wenn der Kolben sich auf seinem Treibhub bewegt, wobei der Teil des Zylinders (104) unter der Öffnungseinrichtung (156), die Kolbenunterseite (130 B) und das Gehäuse (102) in der Nähe des Bodens des Zylinders (104) eine abgedichtete Druckkammer (146) bilden, wodurch die Luft unter dem Kolben (130) und der Öffnungseinrichtung (156) komprimiert wird, um ein Luftpuffer zu bilden, das die Berührung des Gehäuses (102) in der Nähe des Bodens des Zylinders (104) durch den Kolben (130) verhindert.
7. Selbstanlassendes tragbares Werkzeug nach Anspruch 4, bei dem der Abschnitt des Gehäuses (102), der in der Nähe des Bodens des Zylinders (104) liegt, eine Mehrzahl von Einwegrückschlagventilen (174) umfaßt, die sich öffnen, um atmosphärische Luft einzulassen und die Bewegung des Kolbens (130) in seine obere Stellung zu unterstützen, nachdem er angetrieben worden ist und die Verbrennungsgase durch die Öffnungseinrichtung (156) ausgestoßen worden sind, sowie ein Vakuum oberhalb des Kolbens (130) vorhanden ist.

FIG. 1
